Oligomerization of alkenes in a plurality of successive, heterogeneous catalyst zones

- 5 The present invention relates to a process for oligomerizing an alkene stream over a solid catalyst comprising sulfur and nickel.

Alkenes having from 2 to 6 carbon atoms and mixtures thereof, in particular alkenes having 4 carbon atoms, are available in large
10 quantities both from FCC plants and from steam crackers. The C₄ fraction, i.e. the mixture of butenes and butanes, obtained in each case is, after the isobutene has been separated off, particularly well suited to the preparation of oligomers, in particular octenes and dodecenes. Both the octenes and the
15 dodecenes are, after hydroformylation and subsequent hydrogenation to form the corresponding alcohols, used, for example, for the preparation of plasticizers or surfactant alcohols.

20 In the case of plasticizer alcohols, the degree of branching generally has an effect on the properties of the plasticizer. The degree of branching is described by the iso index, which indicates the mean number of methyl branches in the respective fraction. Thus, for example, n-octenes contribute 0,
25 methylheptenes contribute 1 and dimethylhexenes contribute 2 to the iso index of a C₈ fraction. The lower the iso index, the more linear are the molecules in the respective fraction. The higher the linearity, i.e. the lower the iso index, the higher the yields in the hydroformylation and the better the properties of
30 the plasticizer prepared therewith. A lower iso index leads, for example, in the case of phthalate plasticizers, to a reduced volatility and in the case of flexible PVC formulations containing these plasticizers, to improved cold fracture behavior.

35 The conversion of alkenes into low molecular weight oligomers over nickel- and sulfur-containing heterogeneous catalysts is prior art. Catalysts suitable for this purpose are described below.

40 However, the previously known processes of this type have the disadvantage that because of the decreasing alkene content of the feed stream in the direction of the reactor outlet, a satisfactory conversion of the alkenes into relatively unbranched
45 alkenes has hitherto generally only been possible if the temperature is increased in the outlet end of the catalyst bed or

if a more active catalyst is used in this region or the total catalyst volume is increased.

It is an object of the present invention to remedy these
5 disadvantages of the prior art by means of an improved catalyst bed.

We have found that this object is achieved by a process for oligomerizing an alkene stream over a solid catalyst comprising
10 sulfur and nickel, wherein the oligomerization is carried out in two or more successive catalyst zones and the molar ratio of sulfur to nickel in the first catalyst zone is less than 0.5 and that in the last catalyst zone is 0.5 or more and, in the case of further catalyst zones between the first and last catalyst zones,
15 the molar ratio of sulfur to nickel in each catalyst zone is not less than that in the immediately preceding catalyst zone, based on the main flow direction of the feed stream.

For the purposes of the present invention, the term "oligomers"
20 refers to dimers, trimers and higher oligomers of the alkenes. The process of the present invention is particularly useful for preparing dimers of these alkenes.

As starting materials, preference is given to using alkenes
25 having from 2 to 6 carbon atoms, mixtures of such alkenes with one another or mixtures of such alkenes with alkanes. The oligomerization process of the present invention is particularly suitable for the reaction of mixtures of alkenes having 3 and in particular 4 carbon atoms, especially hydrocarbon streams which
30 comprise 1-butene and/or 2-butene and one or more butanes and are essentially free of isobutene.

The reactor is generally a (cylindrical) tube reactor. As an alternative, the reactor used can be a reactor cascade comprising
35 a plurality of, preferably two or three, such tube reactors (subreactors) connected in series, as is known, for example, from WO-A 99/25668 or WO-A 01/72670.

The catalysts over which the oligomerization is carried out are
40 heterogeneous catalysts comprising sulfur and nickel. They are generally known, for example from FR-A 2 641 477, EP-A 272 970, WO-A 95/14647 and WO-A 01/37989, US-A 2,794,842, US-A 3,959,400, US-A 4,511,750 and US-A 5,883,036, which are hereby fully incorporated by reference in respect of the sulfur- and
45 nickel-containing catalysts disclosed therein. Particularly useful catalysts of this type are those which lead to a low degree of branching in the oligomers obtainable therewith,

especially those described in WO-A 95/14647, WO-A 01/37989 and the documents of the prior art cited in this context in these two documents..

- 5 The totality of the catalyst over which the starting material passes in the reactor will hereinafter be referred to as the fixed catalyst bed. If a reactor cascade is employed, the fixed catalyst bed is generally distributed over all the subreactors of the cascade.

10

- The total fixed catalyst bed is, according to the present invention, divided into two or more successive catalyst zones. In this context, a catalyst zone is a section of the fixed catalyst bed in the flow direction of the feed. Such a catalyst zone has a
15 specific sulfur-to-nickel ratio compared to the adjacent catalyst zone(s), especially, when the catalyst zone is located between two other catalyst zones, these two adjacent catalyst zones. In the case of a reactor cascade, a catalyst zone can be located within a single subreactor or can be distributed continuously
20 over two or more successive subreactors, without the fixed catalyst bed in the first and last subreactor having to be made up entirely of this catalyst zone.

- The catalysts of the first and last catalyst zones in particular
25 can each be accommodated in a single reactor or in a cascade of reactors for the purposes of the reaction.

- The feed stream can also be divided and the substreams obtained in this way can be fed to the fixed catalyst bed at different
30 places, for instance when using a reactor cascade at the points between the individual reactors. It is also possible for a substream of the total feed stream to be fed in before the beginning of a catalyst zone or, particularly when a catalyst zone extends from one subreactor to the next in a cascade, at the
35 point at which the catalyst zone is divided between the two subreactors.

- As catalysts for the first catalyst zone, in which the molar ratio of sulfur to nickel is less than 0.5, preference is given
40 to using catalysts of this type as described in WO-A 95/14647 or WO-A 01/37989.

- As catalysts for the last catalyst zone, in which the molar ratio of sulfur to nickel is 0.5 or more, preference is given to using
45 catalysts of this type as described in FR-A 2 641 477; EP-A 272 907, US-A 3,959,400 or US-A 4,511,750, in particular those having a molar ratio of sulfur to nickel of more than 0.8 and very

particularly preferably those having a molar ratio of sulfur to nickel of greater than or equal to 1.

The process of the present invention is preferably carried out
5 over a fixed catalyst bed in which the molar ratio of sulfur to nickel in the first catalyst zone is less than 0.4 and that in the last catalyst zone is more than 0.6.

In a further, preferred embodiment, the process of the present
10 invention is carried out over a fixed catalyst bed in which the molar ratio of sulfur to nickel in the first catalyst zone is less than 0.4 and that in the last catalyst zone is more than 0.8.

15 In a further, preferred embodiment, the process of the present invention is carried out over a fixed catalyst bed in which the molar ratio of sulfur to nickel in the first catalyst zone is less than 0.4 and that in the last catalyst zone is equal to or more than 1.

20 The second and all further catalyst zones of the fixed catalyst bed will hereinafter be referred to as "remaining catalyst zones" to distinguish them from the first catalyst zone.

25 The process of the present invention is preferably carried out in such a way that the alkenes of the feed stream are reacted to an extent of from 50 to 99%, preferably from 65 to 99%, especially from 80 to 99% and in particular from 90 to 99%, in the first catalyst zone in which the molar ratio of sulfur to nickel is
30 less than 0.5.

Furthermore, the process of the present invention is preferably carried out in such a way that the alkenes of the feed stream are reacted to an extent of from 10 to 99%, preferably from 50 to
35 99%, in the remaining catalyst zones.

In a further, preferred embodiment, the process of the present invention is carried out in such a way that the alkenes in the feed stream are reacted to an extent of from 50 to 99% in the
40 first catalyst zone and the alkenes remaining unreacted after this first catalyst zone are reacted to an extent of from 10 to 99% in the remaining catalyst zones.

In a further, preferred embodiment, the process of the present
45 invention is carried out in such a way that the alkenes in the feed stream are reacted to an extent of from 65 to 99% in the first catalyst zone and the alkenes remaining unreacted after

this first catalyst zone are reacted to an extent of from 10 to 99% in the remaining catalyst zones.

5 In a further, preferred embodiment, the process of the present invention is carried out in such a way that the alkenes in the feed stream are reacted to an extent of from 80 to 95% in the first catalyst zone and the alkenes remaining unreacted after this first catalyst zone are reacted to an extent of from 10 to 99% in the remaining catalyst zones.

10

In a further, preferred embodiment, the process of the present invention is carried out in such a way that the alkenes in the feed stream are reacted to an extent of from 80 to 95% in the first catalyst zone and the alkenes remaining unreacted after
15 this first catalyst zone are reacted to an extent of from 50 to 99% in the remaining catalyst zones.

Furthermore, the process of the present invention is preferably carried out in such a way that a total conversion of the alkenes
20 in the feed stream of more than 91%, preferably more than 95% and in particular more than 97%, is achieved over all catalyst zones.

The oligomerization reaction is generally carried out at from 30 to 280°C, preferably from 30 to 190°C and in particular from 40 to
25 130°C, and a pressure of generally from 1 to 300 bar, preferably from 5 to 100 bar and in particular from 10 to 50 bar. The pressure is advantageously selected so that the feed is supercritical and in particular liquid at the temperature set. Different reaction conditions in respect of pressure and/or
30 temperature within these pressure and temperature ranges can be set in the individual tube reactors of a reactor cascade.

The oligomerization process of the present invention can be carried out adiabatically or isothermally.

35

Otherwise, the way of carrying out the process is sufficiently well known to a person skilled in the art, especially from WO-A 99/25668 and WO-A 01/72670, whose relevant contents are hereby fully incorporated by reference.

40

After leaving the reactor, the oligomers formed are separated in a manner known per se from the unreacted hydrocarbons and the latter are, if desired, returned to the process (cf., for example, WO-A 95/14647). The separation is generally carried out
45 by fractional distillation.

Compared to known processes of this type, the process of the present invention leads to a high alkene conversion combined with a low degree of branching of the oligomers obtainable in this way. This effect has hitherto generally been able to be achieved only by increasing the temperature in the later part of the catalyst bed or by using a more active catalyst in this region or by means of an increased total volume of catalyst because of the decreasing alkene content of the gas stream in the direction of the reactor outlet.

10

Examples

I. Catalysts

15 The $\text{Ni}(\text{NO}_3)_2 \cdot 6 \text{H}_2\text{O}$ used came from Fluka.

Catalyst "1a" (S:Ni ratio = 0)

As described in DE-A 43 39 713, Example 1, a sulfur-free catalyst was prepared from 50% by weight of NiO , 37% by weight of SiO_2 and 13% by weight of TiO_2 .

20

Catalyst "1b" (S:Ni ratio = 0.34)

γ -aluminum oxide of the grade "D10-10" from BASF AG (3 mm star

25 extrudates, BET surface area: $202 \text{ m}^2/\text{g}$, water absorption capacity: 0.76 ml/g , loss on ignition: 1.6% by weight) was used as support.

200 g of this support were impregnated at room temperature with 125 ml of a solution of 125 mmol of 96% strength H_2SO_4 and

30 361 mmol of 97% strength $\text{Ni}(\text{NO}_3)_2 \cdot 6 \text{H}_2\text{O}$ in water while stirring. The catalyst obtained in this way was dried in air at 120°C for 10 hours and calcined in air at 500°C for 2 hours. The proportion of nickel ("Ni") was then determined as 9.04% by weight and that of sulfur ("S") was determined as 1.67% by weight, in each case based on the total weight of the catalyst obtained, and the molar ratio of sulfur to nickel ("S:Ni") in the catalyst was determined as 0.34.

35 The sulfur content of the finished catalyst was determined by quantitative infrared analysis of the sulfur dioxide formed on combustion of the catalyst. The nickel content could be obtained by ICP-mass spectrometry.

Catalyst "1c" (S:Ni ratio = 1)

45

γ -aluminum oxide of the grade "D10-10" from BASF AG (4 mm extrudates, BET surface area: 210 m²/g, water absorption capacity: 0.73 ml/g, loss on ignition: 1.8% by weight) was used as support.

- 5 400 g of this support were impregnated at room temperature with a solution of 184 g of NiSO₄ · 6 H₂O in water while stirring. The volume of the water used was chosen in accordance with the water absorption capacity of the support. The catalyst obtained in this way was dried in air at 120°C for 16 hours and calcined in air at
10 500°C for 2 hours. The proportion of nickel ("Ni") was then determined as 7.9% by weight and that of sulfur ("S") was determined as 4.32% by weight, in each case based on the total weight of the catalyst obtained, and the molar ratio of sulfur to nickel ("S:Ni") in the catalyst was determined as 1.

15

II. Oligomerizations

A) Apparatus

- 20 Figure 1 schematically shows an apparatus in which the process of the present invention was, by way of example, carried out continuously at 30 bar. The alkene-containing stream (hereinafter referred to as the "Feed") was fed via F into the adiabatic subreactor R1 and from there conveyed via intermediate cooling ZK
25 to the adiabatic subreactor R2. The subreactors had a length of 4 m and a diameter of 0.08 m, so that they each had a volume of 20 liters; when only 20 liters of catalyst were used, all the catalyst was placed in one of the two subreactors, while the second subreactor contained steatite spheres as inert material.
30 The output from the reactor R2 was worked up by distillation in the column K and the oligomeric product was taken off as bottoms via B. The stream taken from the top of the column K was partly recirculated via Z to the reactor R1, and the other part of this stream was discharged from the apparatus via P (as purge stream).

35

The reaction pressure, which was higher than the pressure at which the raffinate II was supplied, was generated by means of an upstream reactor feed pump and was regulated by means of customary pressure maintenance devices downstream of the reactor.

40

The butene/butane mixtures shown in table 1 were used.

45

Table 1 (Figures are in % by weight based on the total feed stream F)

Mixture	n-butenes	butanes	isobutene
A	78	19.7	2.3
B	54.2	44.8	1
C	56.9	42.3	0.8
D	55.8	44.5	0.7
E	26.8	72.9	0.3
F	26.4	73.2	0.4

B) Experimental procedure

B.1) Reactions over a single catalyst zone

The butene/butane mixtures shown in table 1 were passed at the mean temperature T over the volume Vol of the catalyst Cat located in the apparatus shown in figure 1. The output from the reactor was isolated and analyzed. Further details of the experimental parameters and the results of the experiments are shown in table 2.

B.2) Conversion of the results from B.1 to 2 and 3 catalyst zones

The results from section B.1 were summarized mathematically.

Table 3 shows the results obtained in this way for the sequences according to the present invention (No. 1, 4 and 5) of catalyst zones and for the sequences not according to the present invention (No. 2, 3, 6 and 7) determined for comparative purposes.

It can be seen from the experimental results that combination of two or three catalyst zones to form a fixed catalyst bed in accordance with the present invention gives, at comparable alkene conversions and iso indices of the octenes, a space-time yield in respect of octenes and dodecenes which is from 15 to 33% higher than that obtained in the reaction over catalyst beds which are not in accordance with the present invention. In addition, these results can be obtained at lower reaction temperatures over the catalyst, which has been found on the basis of experience to lead to an increased active life of the catalyst (operating life). This also increases the temperature interval in which the conversion can be increased by increasing the temperature.

Table 2

Mixture	Cat	Vol [l]	T [°C]	Octenes [% by weight]	Dode- cenes [% by weight]	C16+- alkenes [% by weight]	C [%]	Iso I
A	1a	40	60	83.7	13.3	3	70.5	0.95
